1 Project Overview

The project was to create an RPAL interpreter from scratch. Our project involves scanning, parsing, and the running of the CSE machine. In the upcoming pages, we will describe how each module of our interpreter works, including the important functions and inputs and outputs of each module.

1.1 Overall Architecture

The python package consists of 4 folders: lexical_analyser, parser, symbols and engine.

The lexical_analyser folder contains all the logic for the lexical analyser, parser for the parser and engine for the CSE Machine. The symbols folder consists of various classes created for each symbol that could be added to the Control Stack or Data Stack.

1.2 Lexical Analyser

The lexical analyzer takes as an input the name of the file containing the RPAL expression and it outputs a list of tokens.

1.2.1 TokenType.py

All this contains is an enum called TokenType. It specifies the various types of tokens that could be found when scanning an RPAL expression.

1.2.2 Token.py

This is simply a file implementing a Token class which has a simple constructor and a function to return the string representation of a token.

1.2.3 LexicalAnalyser.py

This file contains all the scanning logic. The logic is implemented in a class called LexicalAnaylser. It was a constructor and two important functions: scan() and tokenizeLine(line). The scan() function simply calls tokenizeLine(line) on each line of the input file, and the tokenizeLine function has all the tokenizing logic.

scan() function:

```
def scan(self):
    try:
        p = Path(__file__).parent.parent.parent / self.inputFileName
        input_file = open(p, 'r')
        count = 0
        while True:
            count += 1
            line = input_file.readline()

            if not line:
                break

```

```
13              self.tokenizeLine(line)

14

15          input_file.close()

16

17      except IOError:

18          print("Could not read file {}".format(self.inputFileName))

19

20      filtered_tokens = [

21          token for token in self.tokens if token.type != TokenType.DELETE]

22

23      return filtered_tokens
```

tokenizeLine(line) function, which takes as input a a line and adds the tokens to a running list maintained by the LexicalAnaylser object:

```
1   def tokenizeLine(self, line):
2       digit = r"[0-9]"
3       letter = r"[a-zA-Z]"
4       operatorSymbol = r"[+\-*<>&.@/:=~|$!#%^_\[\]{}\"`?]"
5       punction = r"[();,]"
6
7       identifierPattern = re.compile(
8           letter+r"("+letter+r"|"+digit+r"|"+r"_)*")
9       integerPattern = re.compile(digit+r"+")
10      operatorPattern = re.compile(operatorSymbol+r"+")
11      stringPattern = re.compile(
12          r"'(\t|\n|\\|\"|"+punction+"| |"+letter+"|"+digit+"|"+operatorSymbol+")*'")
13      commentPattern = re.compile(r"//.*")
14      spacesPattern = re.compile(r"[ \t\n]+")
15      punctuationPattern = re.compile(punction)
16
17      currentIndex = 0
18
19      while (currentIndex < len(line)):
20          currentChar = line[currentIndex]
21
22          spaceMatch = re.match(spacesPattern, line[currentIndex:])
23          commentMatch = re.match(commentPattern, line[currentIndex:])
24
25          if commentMatch:
26              comment = commentMatch.group()
27              self.tokens.append(Token(TokenType.DELETE, comment))
28              currentIndex += len(comment)
29              continue
30
31          if spaceMatch:
32              space = spaceMatch.group()
33              self.tokens.append(Token(TokenType.DELETE, space))
34              currentIndex += len(space)
35              continue
36
37          match = re.match(identifierPattern, line[currentIndex:])
38          if match:
39              identifier = match.group()
40
```

```python
            keywords = ["let", "in", "fn", "where", "aug", "or", "not", "gr", "ge", "ls",
                        "le", "eq", "ne", "true", "false", "nil", "dummy", "within", "and", "rec"]

            if identifier in keywords:
                self.tokens.append(Token(TokenType.KEYWORD, identifier))
            else:
                self.tokens.append(Token(TokenType.IDENTIFIER, identifier))

            currentIndex += len(identifier)
            continue

        match = re.match(integerPattern, line[currentIndex:])
        if match:
            integer = match.group()
            self.tokens.append(Token(TokenType.INTEGER, integer))
            currentIndex += len(integer)
            continue

        match = re.match(stringPattern, line[currentIndex:])
        if match:
            string = match.group()
            self.tokens.append(Token(TokenType.STRING, string))
            currentIndex += len(string)
            continue

        match = re.match(operatorPattern, line[currentIndex:])
        if match:
            operator = match.group()
            self.tokens.append(Token(TokenType.OPERATOR, operator))
            currentIndex += len(operator)
            continue

        match = re.fullmatch(punctuationPattern, currentChar)
        if match:
            self.tokens.append(Token(TokenType.PUNCTUATION, currentChar))
            currentIndex += 1
            continue

        print("Unable to tokenize the character: {} at index: {}".format(
            currentChar, currentIndex))
        sys.exit()
```

1.3 Parser

This folder contains all the parsing logic. It takes as input the tokens outputted by the Lexical Analyser, and outputs the Abstract Syntax Tree (AST).

1.3.1 NodeType.py

This contains an enum, listing all the possible types of nodes the AST could have.

1.3.2 Node.py

Simply contains the implementation of the Node class with a constructor and a stringifier.

1.3.3 Parser.py

This contains all the parsing logic encapsulated by a class named Parser. It has several functions. The main ones are parse(), and all of the functions responsible for parsing each production. These functions were written based on the RPAL Phrase Structure Grammar. In addition it has certain helper functions.

parse() function:

```python
def parse(self):
    # To know when we have gotten the last token
    self.tokens.append(Token(TokenType.ENDOFTOKENS, ""))
    self.E()

    if (self.tokens[0].type == TokenType.ENDOFTOKENS):
        return self.AST

    else:
        print("Parsing unsuccessful...")
        print("Remaining unparsed tokens:")
        for token in self.tokens:
            print(token)
        return None
```

Functions for each production in the RPAL Phrase Grammar Structure

```
E      -> 'let' D 'in' E                          => 'let'
       -> 'fn'   Vb+ '.' E                        => 'lambda'
       ->    Ew;
Ew     -> T  'where' Dr                           => 'where'
       -> T;
```

Figure 1: Expression Productions

```python
1   def E(self):
2       n = 0
3       token = self.tokens[0]
4
5       if token.type == TokenType.KEYWORD and token.value in ["let", "fn"]:
6           if token.value == "let":
7               self.tokens.pop(0)
8               self.D()
9
10              if (self.tokens[0].value != "in"):
11                  print("Parse error at E : 'in' expected")
12                  sys.exit()
13
14              self.tokens.pop(0)
15              self.E()
16              self.AST.append(Node(NodeType.let, "let", 2))
17
18          else:
19              self.tokens.pop(0)
20
21              while True:
22                  self.Vb()
23                  n += 1
24
25                  if ((self.tokens[0].type != TokenType.IDENTIFIER) and (self.tokens[0].value != "(")):
26                      break
27
28              if not self.tokens[0].value == ".":
29                  print("Parse error at E : '.' expected")
30                  sys.exit()
31
32              self.tokens.pop(0)
33              self.E()
34              self.AST.append(Node(NodeType.lambda_, "lambda", n+1))
35
36      else:
37          self.Ew()
38
39  def Ew(self):
40      self.T()
41      if (self.tokens[0].value == "where"):
42          self.tokens.pop(0)  # remove the "where"
43          self.Dr()
44          self.AST.append(Node(NodeType.where, "where", 2))
```

```
T       -> Ta ( ',' Ta )+                          => 'tau'
        -> Ta ;
Ta      -> Ta 'aug' Tc                             => 'aug'
        -> Tc ;

```

1.4 Symbols

This is just a folder containing all the files in which classes are implemented for each symbol. This was done while implementing the CSE Machine when we realised that using classes we can easily check what symbol is on the stack using isinstance().

1.5 Engine

This folder contains the logic of the CSE Machine. It takes as input to it, the AST generated from the parser, and outputs the result of the RPAL expression. In this section, for most of the classes we have created Factory classes. This was to abstract out the task of construction to a seperate class. That way, when a factory class returns an instance of a class we want, it has already been initialised to its required state.

1.5.1 NodeAndNodeFactory.py

This contains the logic of getting a node given certain arguments, and standardizing a node.

Logic for getting a node: This was implemented using the standardization rules in the lecture slides.

```python
def getNode(*args):
    node = Node()
    node.data = args[0]
    node.depth = args[1]

    if len(args) > 2:
        node.parent = args[2]
        node.children = args[3]
        node.isStandardized = args[4]

    return node
```

Function to standardize a node:

```python
def standardize(self):
    if not self.isStandardized:
        for child in self.children:
            child.standardize()

        # In accordance with CSE Rules 6 - 11, we don't standardize "tau", "UOp", "BOp", ",", and "->" nodes

        match self.data:
            # Standardizing "let" node
            case "let":
                E = self.children[0].children[1]
                E.parent = self
                E.depth = self.depth + 1
                P = self.children[1]
                P.parent = self.children[0]
                P.depth = self.depth + 2
                self.children[0].data = "lambda"
                self.children[1] = E
                self.children[0].children[1] = P
                self.data = "gamma"

            # Standardizing "where" node
            case "where":
```

```
24              # Here, we can simply convert the "where" node into a "let" node and standardize it as above
25              P = self.children[0]
26              self.children[0] = self.children[1]
27              self.children[1] = P
28
29              self.data = "let"
30              self.standardize()
31
32          case "function_form":

1.5.2 ASTAndASTFactory.py

This file contains the details of the AST. The ASTFactory has a static method getAST(data). Here, data is the AST that was outputted from the Parser. The getAST function converts this string representation of the AST into an actual abstract data structure, and returns the root node.

getAST(data) function:

```python
1    @staticmethod
2    # A function that takes in the string AST, and returns the root of the AST
3    # Each node in the AST will have a parent attribute as well as a list containing all its children
4    def getAST(data):
5        root = NodeFactory.getNode(data[0], 0)
6        prevNode = root
7        depth = 0
8
9        for string in data[1:]:
10           d = 0
11
12           while string[d] == '.':
13               d += 1
14
15           currNode = NodeFactory.getNode(string[d:], d)
16
17           if depth < d:
18               prevNode.children.append(currNode)
19               currNode.parent = prevNode
20
21           else:
22               while prevNode.depth != d:
23                   prevNode = prevNode.parent
24
25               prevNode.parent.children.append(currNode)
26               currNode.parent = prevNode.parent
27
28           prevNode = currNode
29           depth = d
30
31       return AST(root)
```

1.5.3   CSEMachineAndCSEMachineFactory.py

There are two classes implemented here: CSEMachineFactory and CSEMachine. All the background work is being done by the CSEMachineFactory class. And the CSEMachine does what it's supposed to do according to the lecture notes: Modify the Control, Stack, and Environment according to the CSE machine rules.

The functions of CSEMachineFactory are :

- **getSymbol(node)**

  This functions returns an instance of the appropriate symbol (based on the node inputted to the function) out of the symbol classes in the aforementioned Symbols folder.

```python
def getSymbol(self, node):
    match node.data:
        case "not" | "neg":
            return UOp(node.data)

        case "+" | "-" | "*" | "/" | "**" | "&" | "or" | "eq" | "ne" | "ls" | "le" | "gr" | "ge" | "aug":
            return BOp(node.data)

        case "gamma":
            return Gamma()

        case "tau":
            return Tau(len(node.children))

        case "<Y*>":
            return YStar()

        case _:
            if node.data.startswith("<ID:"):
                return Id(node.data[4:len(node.data)-1])
            elif node.data.startswith("<INT:"):
                return Int(node.data[5:len(node.data)-1])
            elif node.data.startswith("<STR:"):
                return Str(node.data[6:len(node.data)-2])
            elif node.data.startswith("nil"):
                return Tup()
            # Since we're using Python, we need to capitalize the boolean or else it will cause problems
            elif node.data.startswith("true"):
                return Bool("True")
            elif node.data.startswith("false"):
                return Bool("False")
            elif node.data.startswith("<dummy>"):
                return Dummy()
            else:
                return Err(f"No symbol found for given node: {node.data}")
```

- **getB(node)**

  A 'B' is the part of the conditional operator that evaluates to a truthvalue. This function is used to create the B symbol and initializing its list of symbols with the pre-order traversal of that node.

```
1   def getB(self, node):
2       b = B()
3       b.symbols = self.getPreOrderTraversal(node)
4
5       return b
```

- **getDelta(node)**

  This function creates a Delta symbol and initializes its list of symbols to the pre-order traversal of the delta node.

```
1   def getDelta(self, node):
2       delta = Delta(self.j)
3       self.j += 1
4       delta.symbols = self.getPreOrderTraversal(node)
5
6       return delta
```

- **getLambda(node)**

  This creates a Lambda symbol. The lambda symbol has an attribute called delta, which is the preorder traversal of the right child of the lambda. This connection is made within this function.

```
1   def getLambda(self, node):
2       lambda_ = Lambda(self.i)
3       self.i += 1
4       lambda_.delta = self.getDelta(node.children[1])
5
6       if node.children[0].data == ",":
7           for identifier in node.children[0].children:
8               lambda_.identifiers.append(
9                   Id(identifier.data[4:len(identifier.data)-1]))
10      else:
11          bounded_var = node.children[0]
12          lambda_.identifiers.append(
13              Id(bounded_var.data[4:len(bounded_var.data)-1]))
14
15      return lambda_
```

- **getPreOrderTraversal(node)**

```
1   def getPreOrderTraversal(self, node):
2       symbols = []
3       if node.data == "lambda":
4           symbols.append(self.getLambda(node))
5
6       elif node.data == "->":
7           symbols.append(self.getDelta(node.children[1]))   # delta then
8           symbols.append(self.getDelta(node.children[2]))   # delta else
9           symbols.append(Beta())
```

```
10            symbols.append(self.getB(node.children[0]))
11
12        else:
13            symbols.append(self.getSymbol(node))
14            for child in node.children:
15                symbols.extend(self.getPreOrderTraversal(child))
16
17        return symbols
```

- **getControl(ast)**

  Sets control to its initial state (containing only e0 and delta1) and returns control.

```
1    def getControl(self, ast):
2        control = []
3        control.append(self.e0)
4        control.append(self.getDelta(ast.root))
5
6        return control
```

- **getStack()**

  Sets stack to its initial state (containing only e0) and returns it.

```
1    def getStack(self):
2        stack = []
3        stack.append(self.e0)
4
5        return stack
```

- **getEnv()**

  Returns a list, containing only e0, other envs to be added as the CSE machine executes.

```
1    def getEnv(self):
2        return [self.e0]
```

- **getCSEMachine(ast)**

  Initializes and returns a CSE machine with it's control, stack and env set to the proper initial state.

```
1    def getCSEMachine(self, ast):
2        return CSEMachine(self.getControl(ast), self.getStack(), self.getEnv())
```

The functions of CSEMachine are :

- **execute()**

  This is the main function, and it encapsulates all the logic of the CSE machine. If this functions successfully finishes execution, you will have the control empty and the stack containing the result of the RPAL expression.

```python
def execute(self):
    currEnv = self.env[0]
    j = 1

    while self.control:
        # print("\nControl stack: ")
        # self.printControl()

        # print("\nData stack: ")
        # self.printStack()

        # Pop the control
        currentSymbol = self.control.pop()

        # CSE Rule 1
        if isinstance(currentSymbol, Id):
            Ob = currEnv.lookup(currentSymbol)
            self.stack.insert(0, Ob)

        # CSE Rule 2
        elif isinstance(currentSymbol, Lambda):
            lambda_ = currentSymbol
            lambda_.environment = currEnv.index
            self.stack.insert(0, lambda_)

        elif isinstance(currentSymbol, Gamma):
            # Get stack-top
            stackTop = self.stack.pop(0)
            # CSE Rule 4
            if isinstance(stackTop, Lambda):
                lambda_ = stackTop
                e = E(j)
                j += 1

                if (len(lambda_.identifiers) == 1):
                    e.values[lambda_.identifiers[0]] = self.stack.pop(0)

                # CSE Rule 11
                else:
                    tup = self.stack.pop(0)

                    i = 0
                    for id in lambda_.identifiers:
                        e.values[id] = tup.symbols[i]

```

- **applyUOp and applyBOp**

  Functions to apply unary and binary operators on their respective operands. This functions is a helper function for execute()

```python
def applyUOp(self, rator, rand):
    if rator.data == "neg":
        return Int(str(-1 * int(rand.data)))

    elif rator.data == "not":
        return Bool(str(not eval(rand.data)))

    else:
        return Err("Unknown unary operator encountered!")

def applyBOp(self, rator, rand1, rand2):
    if rator.data == "+":
        return Int(str(int(rand1.data) + int(rand2.data)))

    elif rator.data == "-":
        return Int(str(int(rand1.data) - int(rand2.data)))

    elif rator.data == "*":
        return Int(str(int(rand1.data) * int(rand2.data)))

    elif rator.data == "/":
        return Int(str(int(rand1.data) / int(rand2.data)))

    elif rator.data == "**":
        return Int(str(int(rand1.data) ** int(rand2.data)))

    elif rator.data == "&":
        return Bool(str(eval(rand1.data) and eval(rand2.data)))

    elif rator.data == "or":
        return Bool(str(eval(rand1.data) or eval(rand2.data)))

    elif rator.data == "eq":
        return Bool(str(rand1.data == rand2.data))

    elif rator.data == "ne":
        return Bool(str(rand1.data != rand2.data))

    elif rator.data == "ls":
        return Bool(str(int(rand1.data) < int(rand2.data)))

    elif rator.data == "le":
        return Bool(str(int(rand1.data) <= int(rand2.data)))

    elif rator.data == "gr":
        return Bool(str(int(rand1.data) > int(rand2.data)))

    elif rator.data == "ge":
        return Bool(str(int(rand1.data) >= int(rand2.data)))

    elif rator.data == "aug":
```

```
52            if not isinstance(rand1, Tup):
53                return Err("'aug' operator expects either tuple or nil")
54
55            if isinstance(rand2, Tup):
56                rand1.symbols.extend(rand2.symbols)
57            else:
58                rand1.symbols.append(rand2)
59
60            return rand1
61
62        else:
63            return Err("Unknown binary operator encountered!")
```

- **getStringTuple(tup)**

  This functions returns the string representation of a tuple. This is done in case the RPAL program requires a tuple to be printed, or the value of the RPAL program is a tuple.

```
1   def getStringTuple(self, tup: Tup):
2       result = "("
3
4       for symbol in tup.symbols:
5           if isinstance(symbol, Tup):
6               result += self.getStringTuple(symbol) + ", "
7
8           else:
9               # We need to do the following because in RPAL, truthvalues are in lowercase, but in Python, the first
10              # letter is capitalized.
11              data = symbol.data.lower() if isinstance(symbol, Bool) else symbol.data
12              result += data + ", "
13
14      # Remove the ', ' from the last tuple element
15      result = result[0:len(result)-2] + ")"
16      return result
```

- **getResult()**

  This function runs the execute method and returns the answer (stack-top after execution).

```
1   def getResult(self):
2       self.execute()
3       answer = self.stack.pop(0)
4
5       if (isinstance(answer, Tup)):
6           return self.getStringTuple(answer)
7
8       # We need to do the following because in RPAL, truthvalues are in lowercase, but in Python, the first
9       # letter is capitalized.
10
11      return answer.data.lower() if isinstance(answer, Bool) else answer.data
```

2 How to run

2.1 Prerequisites

1. You need to have Python3 installed on your machine.

2.2 Steps

1. Extract the contents of the zipped folder onto your machine.

2. Either copy the input file containing the RPAL expression into the folder, or enter the program into the ”input_file.txt” file. The file containing the RPAL program must be directly under the PROJECT-CS3513 folder.

3. You can either run the python file directly from the command line, or you can use a make command.

    (a) To use the terminal :

        i. Open a terminal in the Project-CS3513 directory, and run the following command :

```
python ./myrpal.py <name of file containing RPAL expression>
```

        This will run the RPAL program. If a Print is called in the RPAL program, the printed value will be displayed on the console.

        ii. If you want to print the AST (Abstract Syntax Tree), you need to add a '-ast' flag to the above command. Keep in mind that this will only print the AST for the program, and the program will not actually execute. The new terminal command will look like :

```
python ./myrpal.py <name of file containing RPAL expression> -ast
```

    (b) To use the make command :

        i. Open a terminal in the Project-CS3513 directory, and run the following command :

```
make run filename="<whatever_the_file_name_is>.txt"
```

        This will run the RPAL program. If a Print is called in the RPAL program, the printed value will be displayed on the console.

        ii. If you want to print the AST (Abstract Syntax Tree), you need to use a different target: ast The new terminal command will look like :

```
make ast filename="<whatever_the_file_name_is>.txt"
```
